

Cut-off vs. avoided burden
in metals' recycling:
in view of environmental sustainability,
risk perception and eco-efficiency

Theses and question

- Modelling of recycling of metals is a contentious issue and involves value judgements
- Two principle opposing approaches are:
 - avoided burden approach
 - cut-off approach
- Which sustainability concepts do they serve?
- Which risk perception is related to them?
- What are their implications on eco-efficiency?

Sustainability definitions

- **Weak sustainability:**
Manufactured capital of equal value can take the place of natural capital
- **Strong sustainability:**
The existing stock of natural capital must be maintained and enhanced because the functions it performs cannot be duplicated by manufactured capital

Decision situations

- Information for decision support includes everything that can be influenced by the decision
- In economics:
Costs, that cannot be influenced by a decision, should not be considered
=> sunk costs
- In LCA:
principle applicable and applied on environmental impacts

Modelling of recycling according to ISO 14041/44

Distinction between

- *closed-loop allocation procedure*

Use of recycled materials in identical products or open-loop but no change in inherent properties

First closed-loop cycle may be treated like open-loop recycling

- *open-loop allocation procedure*

Use of recycled materials in other products

Modelling of recycling according to ISO 14041/44 (cont.)

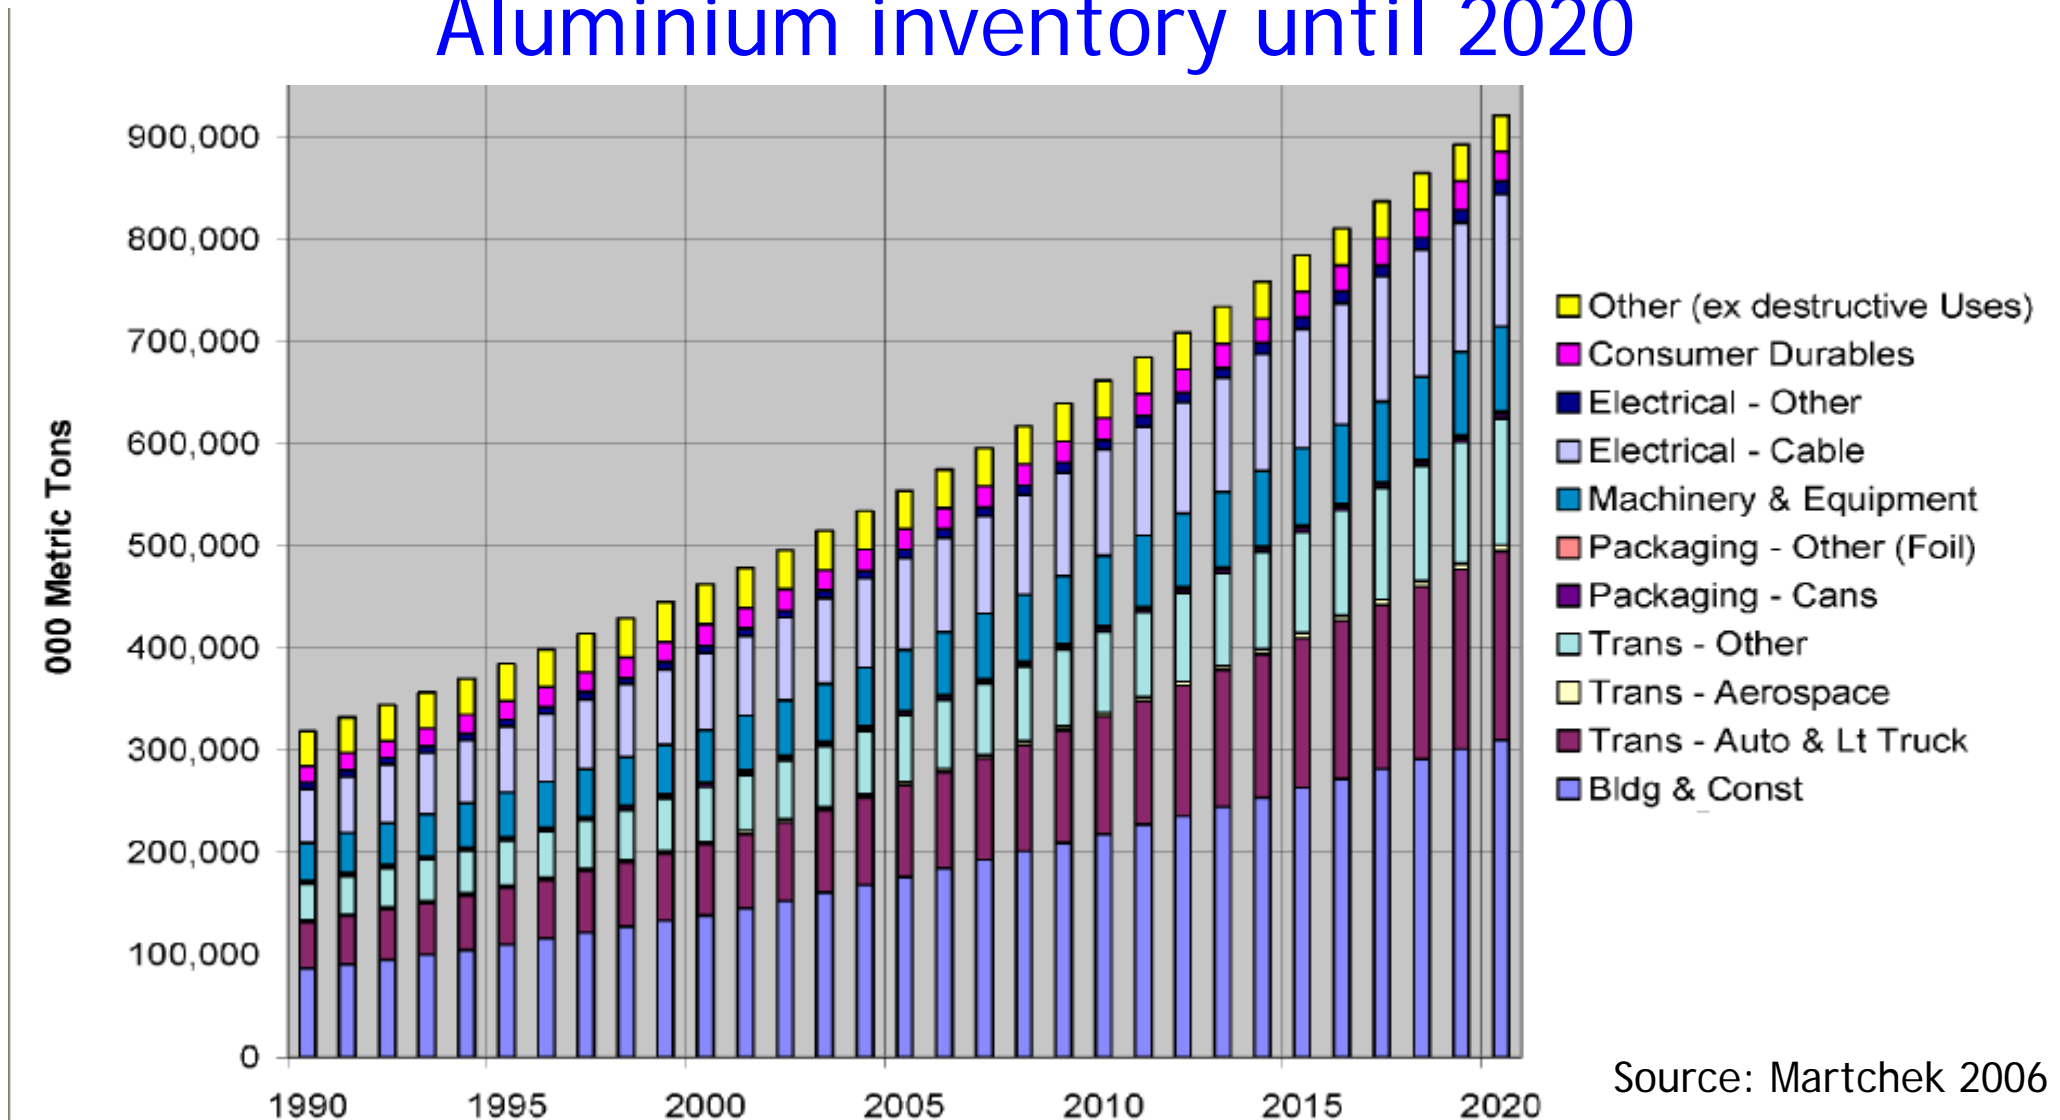

- closed-loop:
allocation is avoided, because secondary material replaces primary material
- open-loop:
basis for allocation:
 - physical properties (e.g., mass)
 - economic value (market value of scrap compared to price of primary material)
 - number of subsequent uses of the recycled material

Example: Aluminium flows 2003

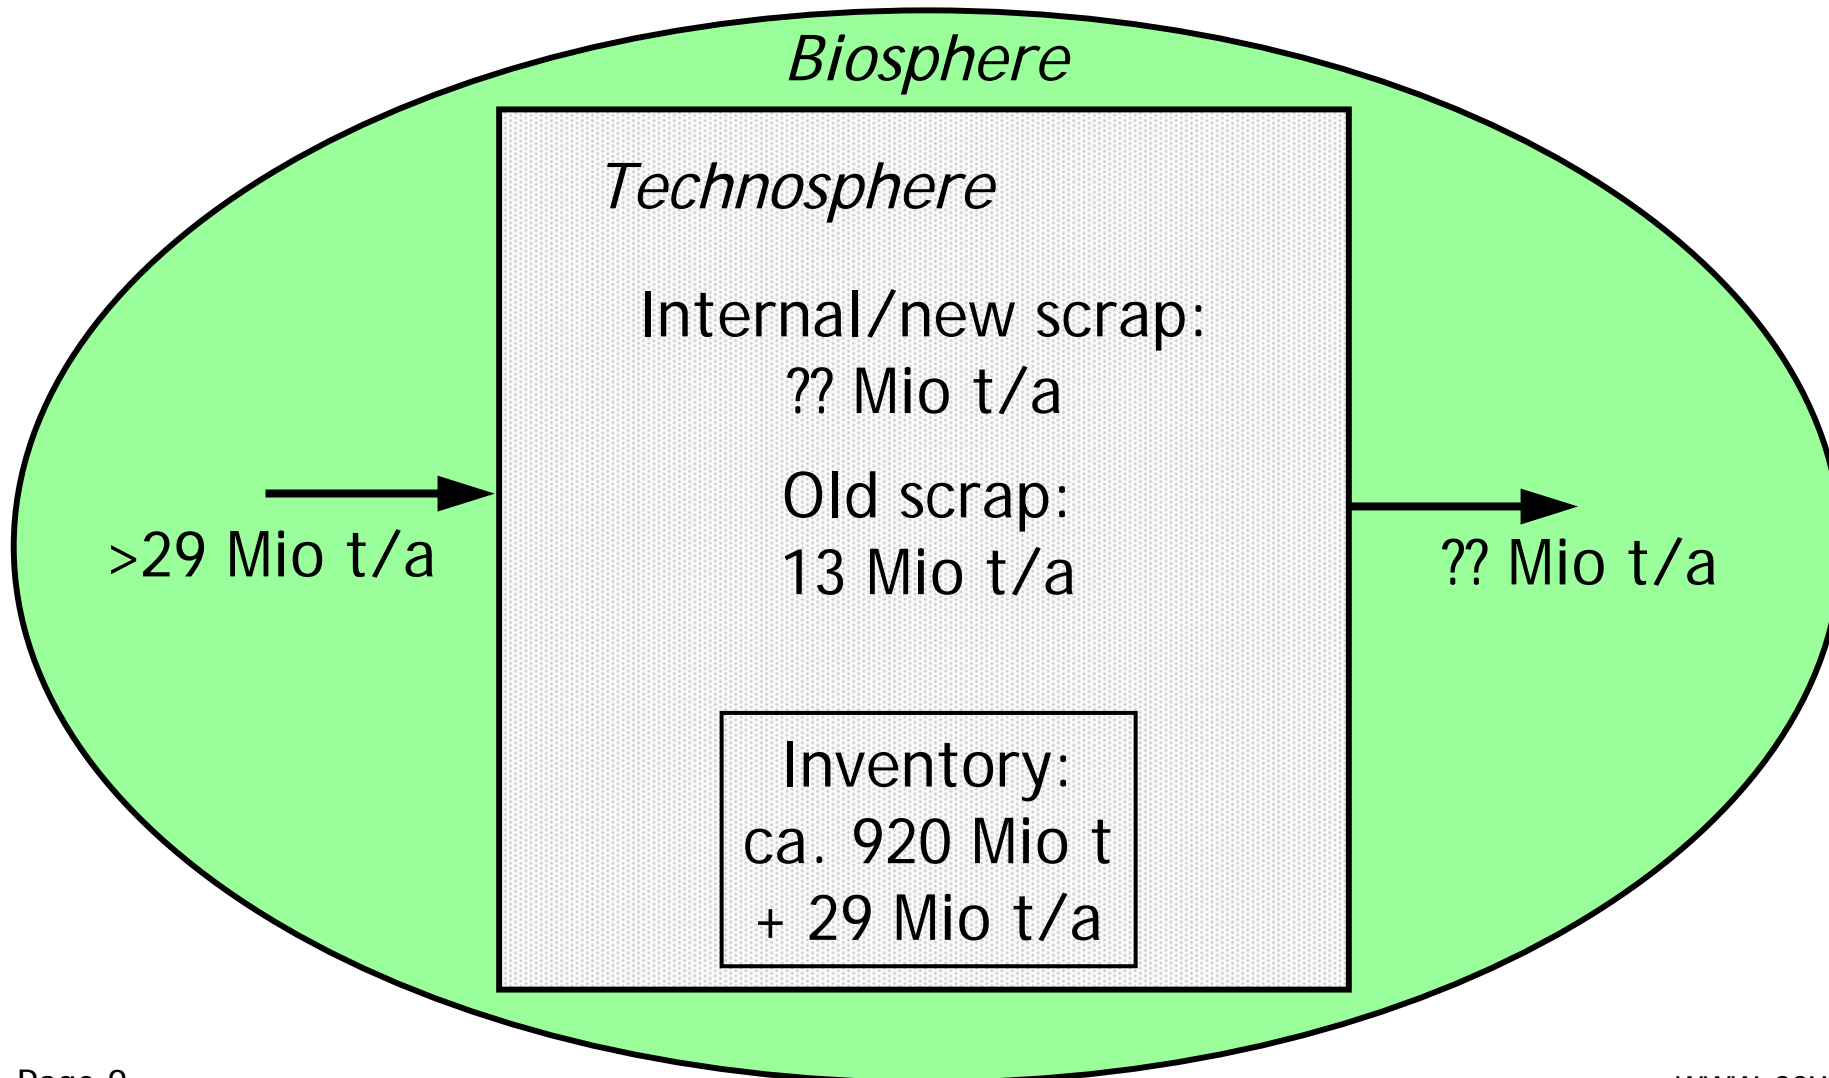

Source: Martchek 2006

Industry expert projection of Aluminium inventory until 2020

Source: Martchek 2006

Predicted Aluminium flows 2020

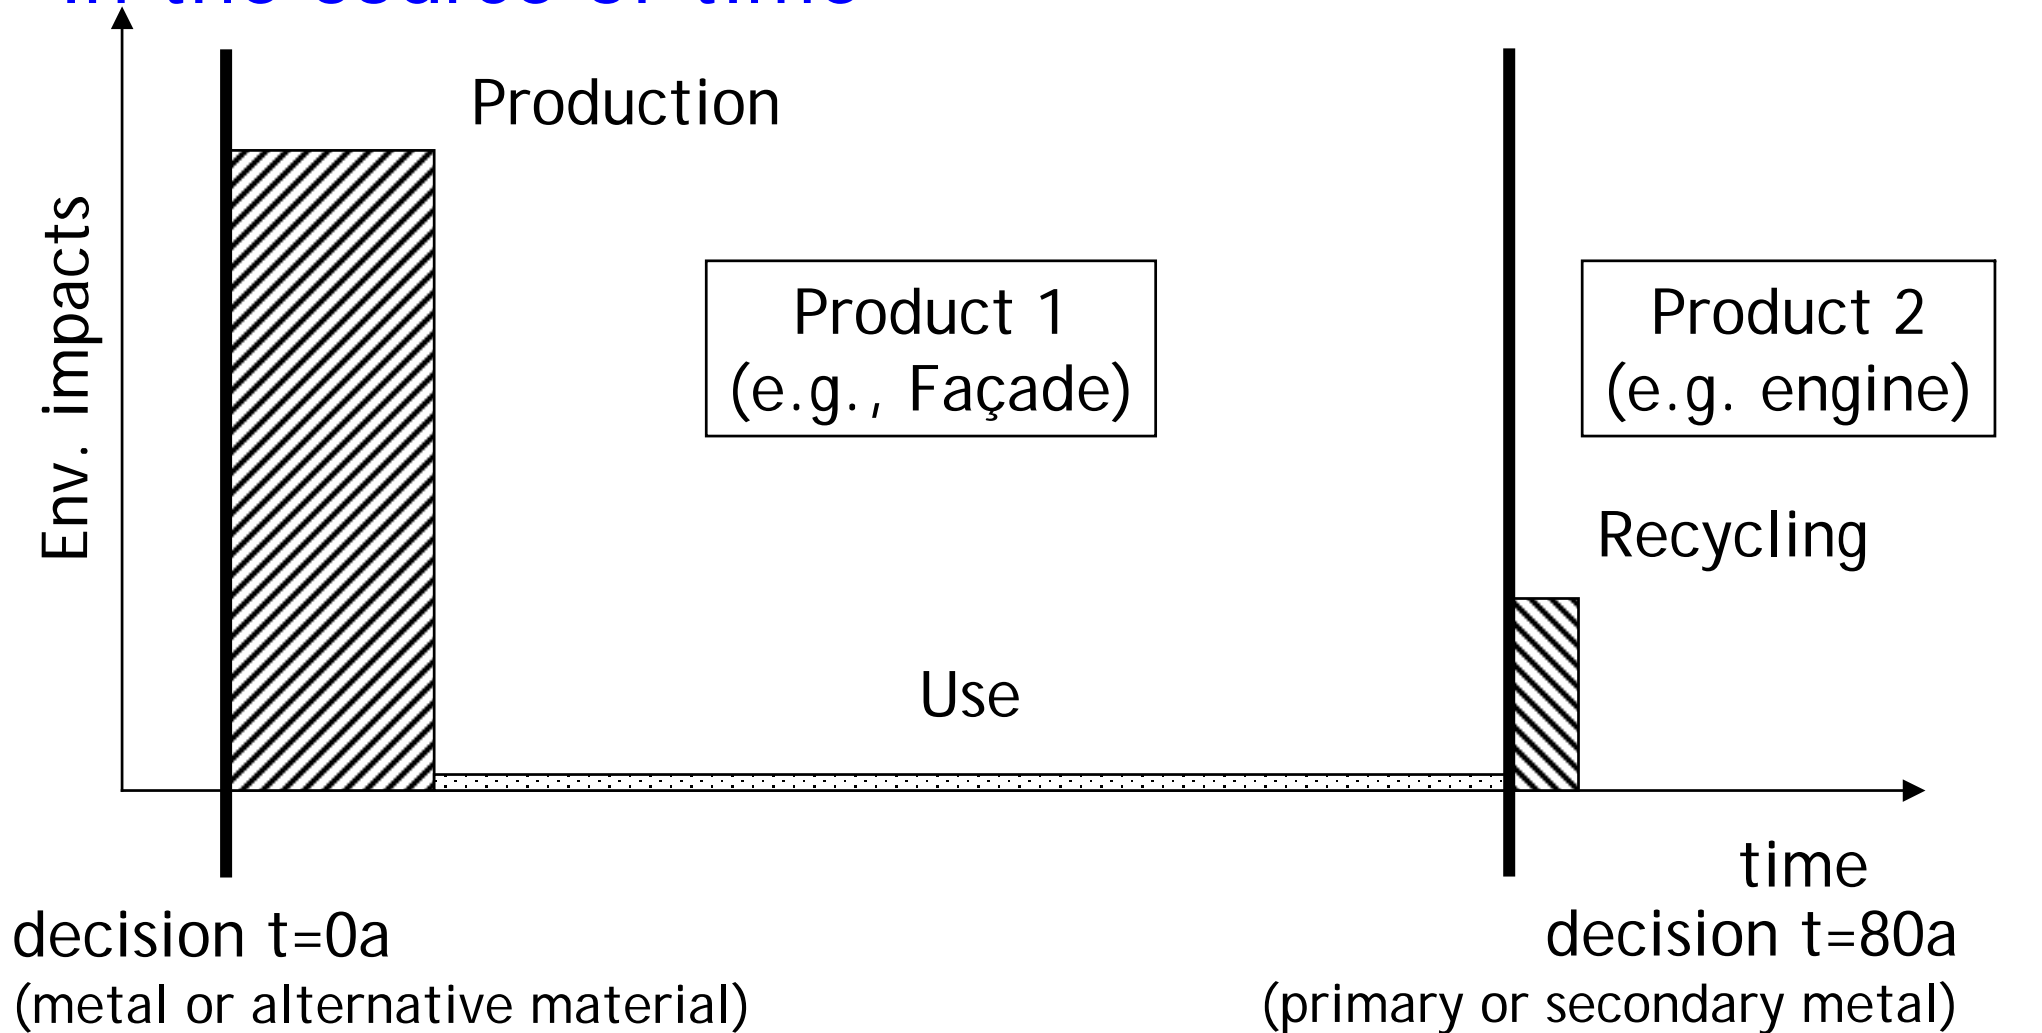

Greenhouse gas emissions caused by Aluminium production and recycling

- Primary aluminium (production 2003):
320 Mio. tons CO₂-eq per year
- Secondary aluminium (reference year 2003):
20 Mio. tons CO₂-eq per year

In comparison:

- Greenhouse gas emissions of Poland:
384 Mio. tons CO₂-eq per year (2004)

Environmental impacts of a metal product in the course of time

Avoided burden approach

- Recycling of a metal avoids extraction and manufacturing of primary metal
- All avoided expenses and emissions are completely attributed to the product that delivers the metal scrap after its service life (common practice)

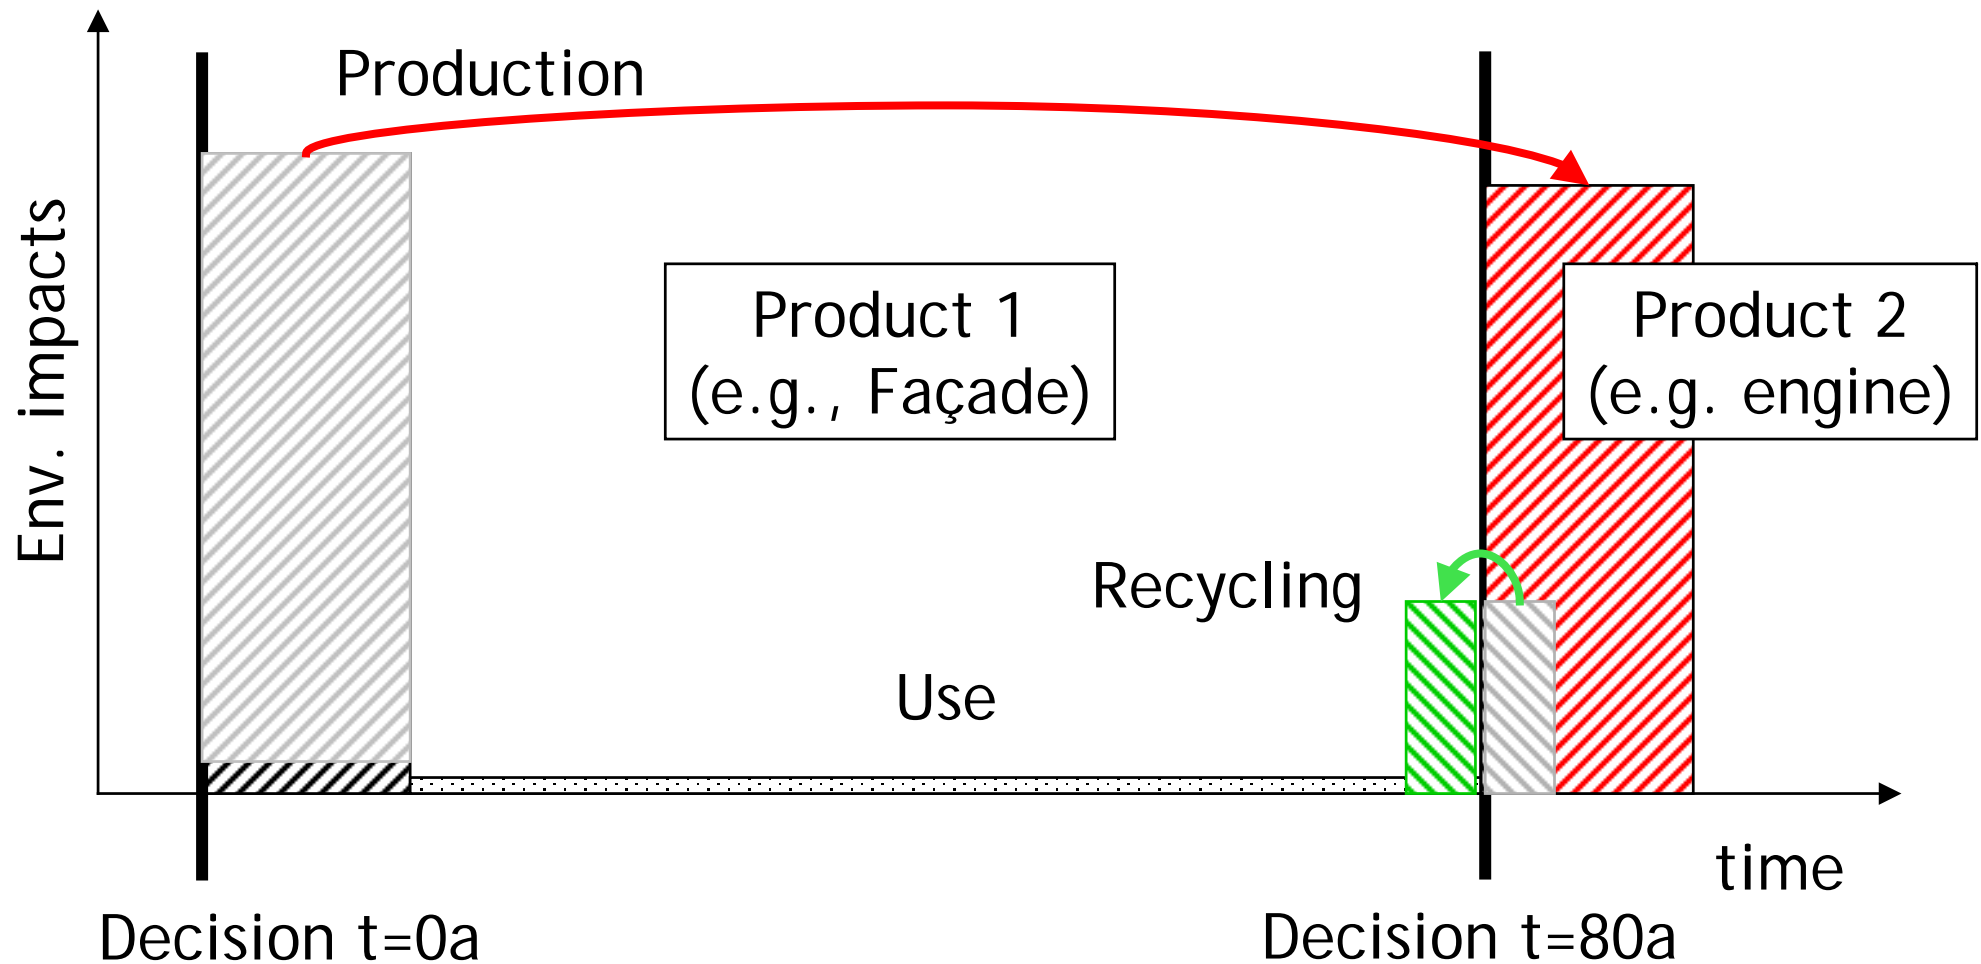

=> Precycling

Environmental impacts modelled according to the avoided burden approach

Interpretation of the avoided burden approach

- Future Generations grant an “environmental loan”, used as credits on primary metal used today.
- In return, future generations receive concentrated metal in infrastructures and consumer durables
- Approach in line the weak sustainability concept
- Aluminium example
 - “Environmental loan”:
about 300 Mio. tons of CO₂-eq per year
 - “inheritance”:
about 19 Mio. tons concentrated aluminium per year

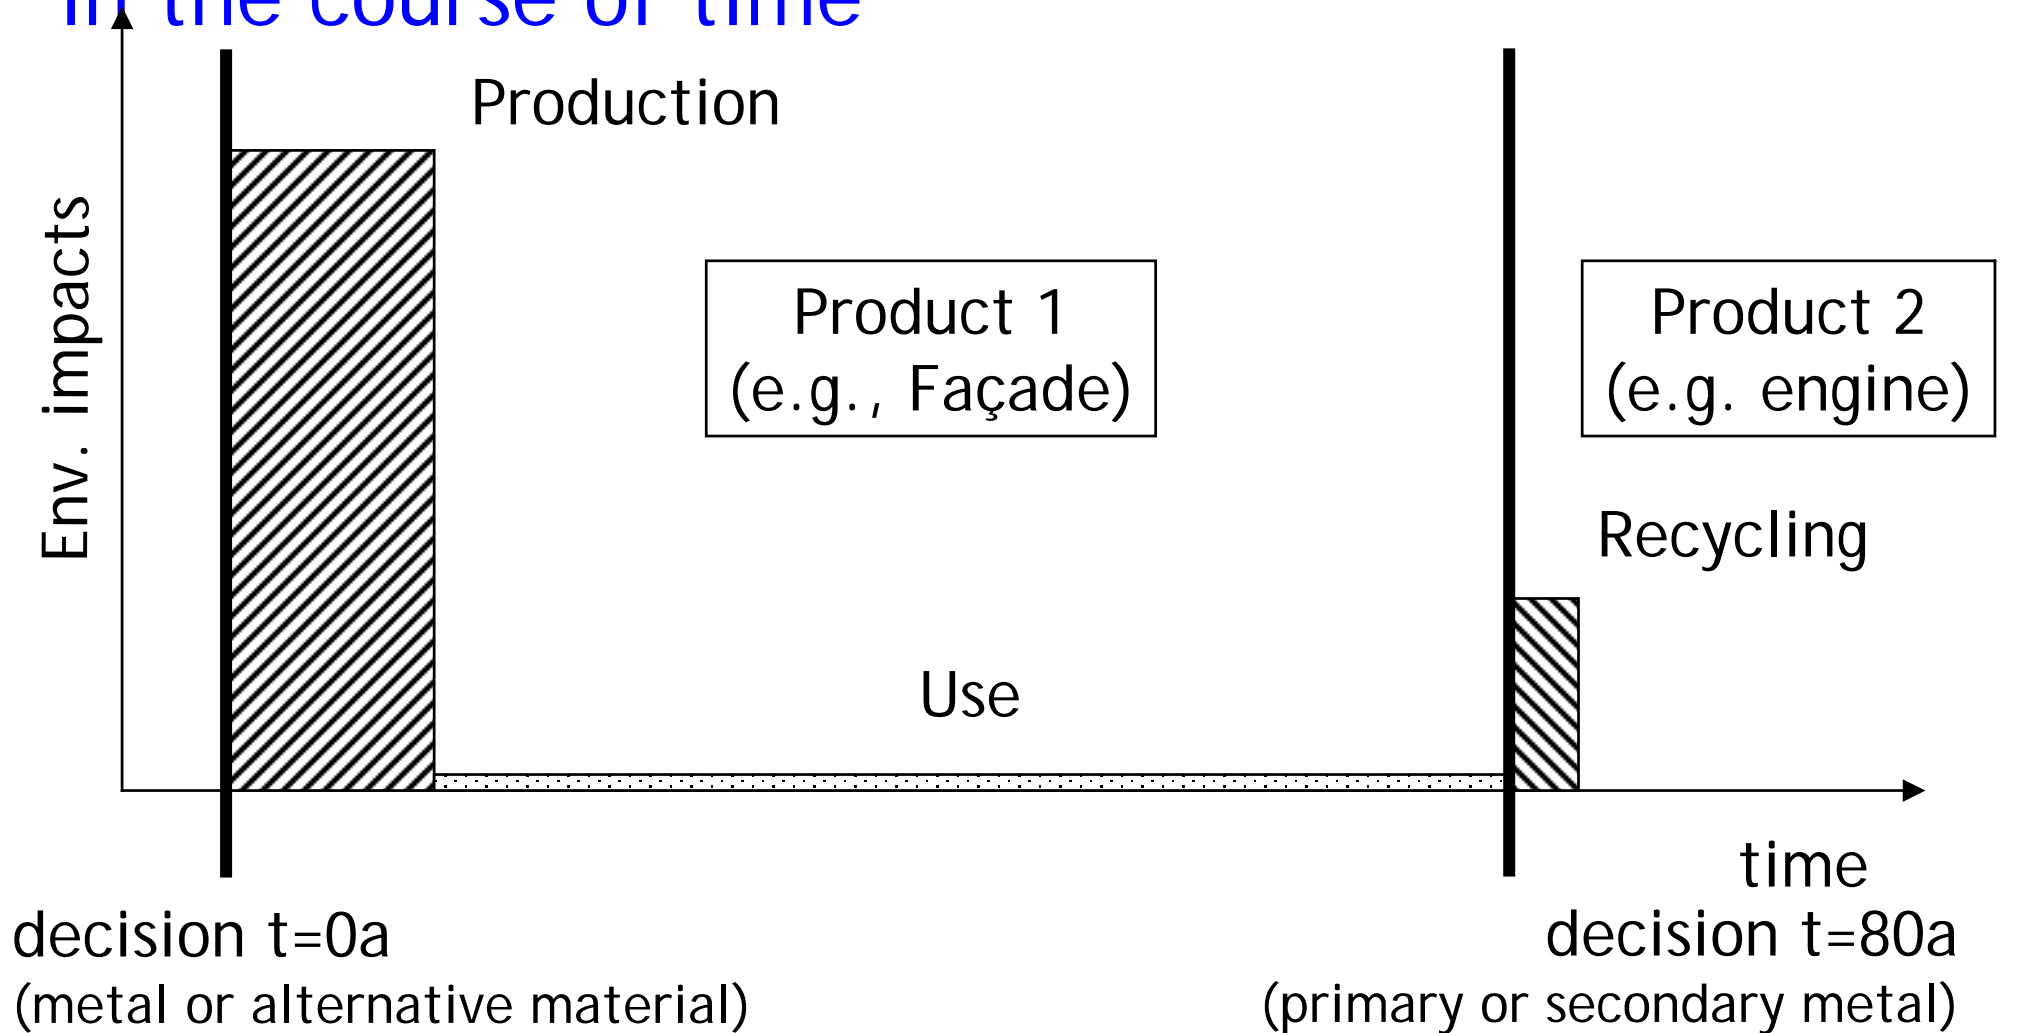

Effects of the avoided burden approach

- Actual environmental impacts occurring today are not recognized, because impacts are substantially reduced by credits granted
- Environmental impacts postponed into the future but already occurred in the past (or present) will not be considered in future decisions (sunk impacts!)

Cut off approach

- First use of (primary) metal bears environmental impacts of extraction and refinement
- Secondary metals are considered according to the recycled content in the product at issue
- Metal scrap leaves system without burdens
- No credits granted

Environmental impacts of a metal product in the course of time

decision t=0a
(metal or alternative material)

decision t=80a
(primary or secondary metal)

Interpretation of cut off approach

- Prompt accounting of actually occurring environmental impacts
=> No burden shifting into the future
- No compensation of increased amount of concentrated metal with reduced natural capital
In line with strong sustainability concept
- Secondary metals are considered according to the recycled content in the product at issue

Eco-efficiency concept: Aluminium prices (2003)

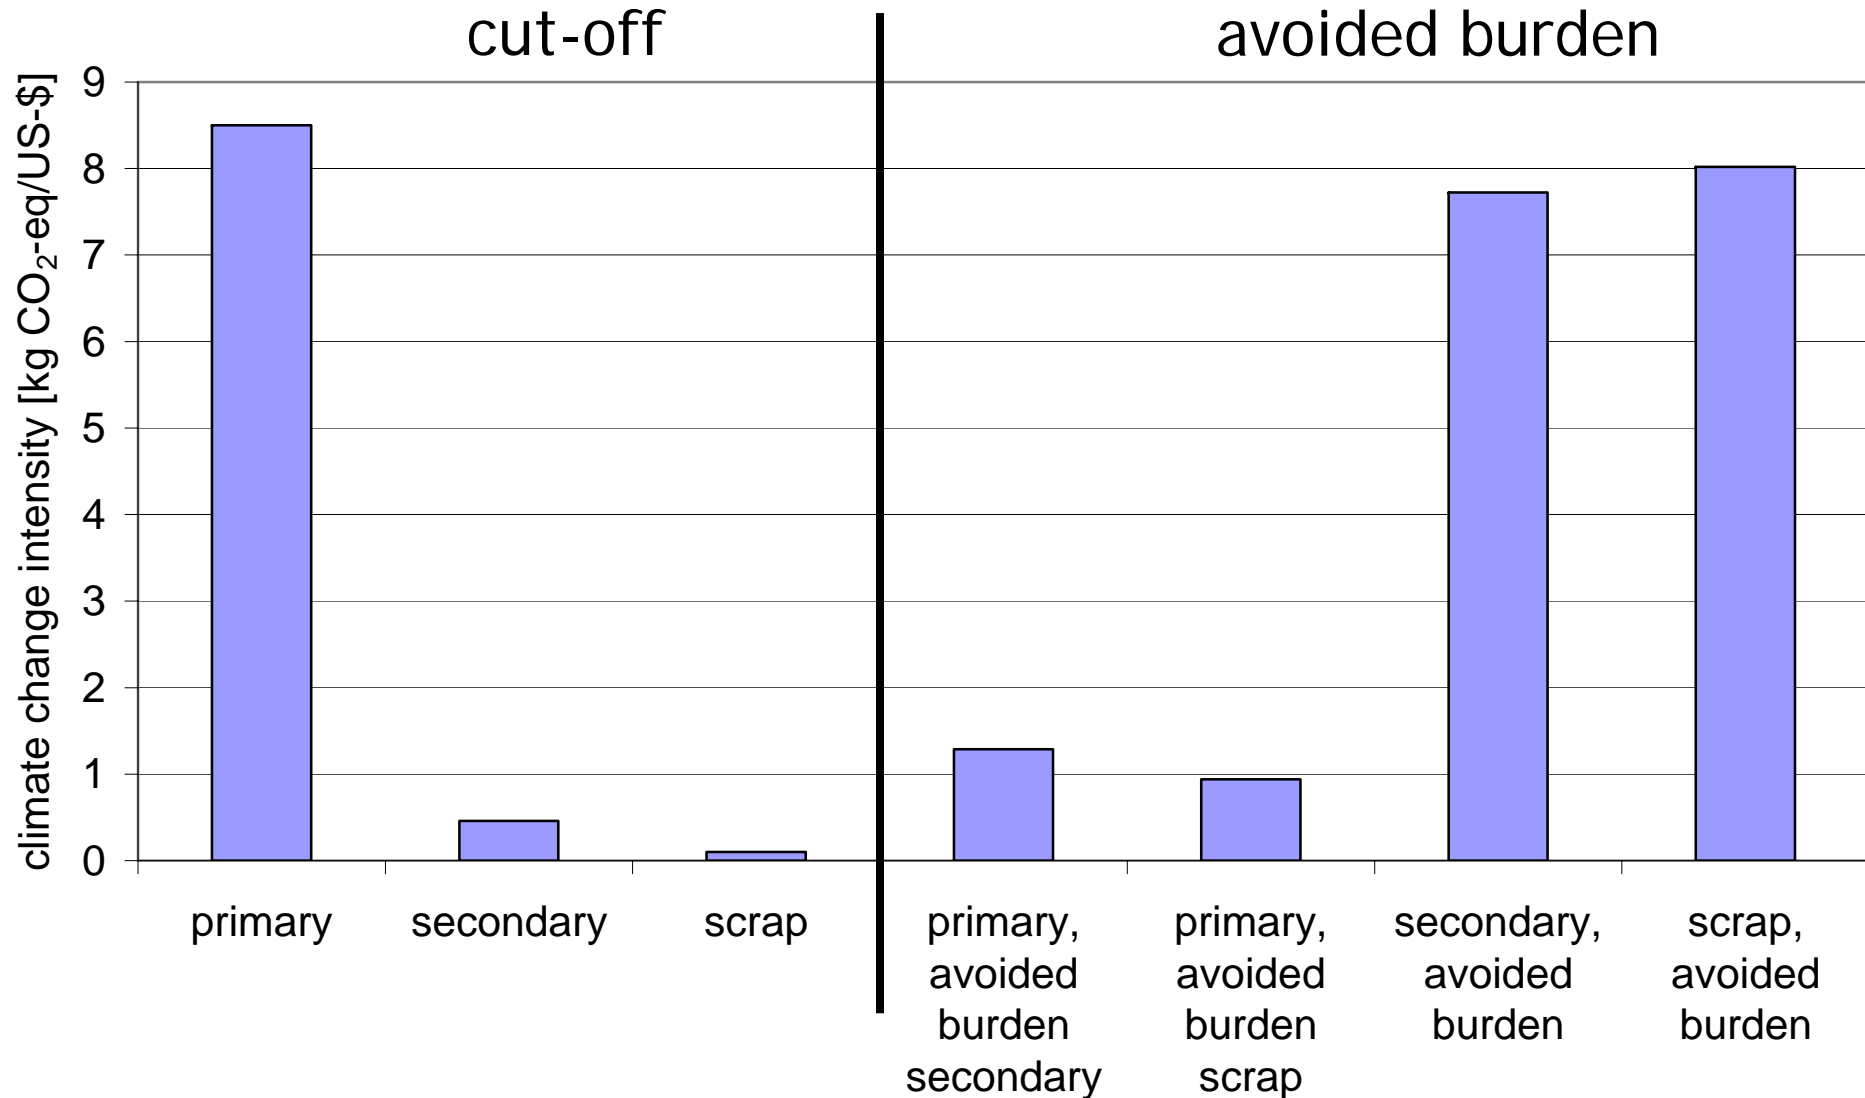

- **Primary Aluminium:** 1'400 \$/t
(London Metals Exchange, Nov 2002 - Mar 2003)
- **Secondary Aluminium:** 1'350 \$/t
(London Metals Exchange, Nov 2002 - Mar 2003)
- **Aluminium scrap:** 765 \$/t
(bulk scrap from decommissioned building, Nov 2002 - Mar 2003)
- **“Avoided burden” primary Aluminium prices:**
 $(1-0.9) * \text{primary} + 0.9 * \text{secondary/scrap}$
(assuming 90% recycling efficiency)

prices and climate change impact of Aluminium (2002/2003)

| | price | climate change impact |
|------------------------------------|----------|---------------------------|
| | US-\$/kg | kg CO ₂ -eq/kg |
| primary | 1.40 | 11.9 |
| secondary | 1.35 | 0.618 |
| scrap | 0.76 | 0.077 |
| primary, avoided burden, secondary | 1.36 | 1.75 |
| primary, avoided burden, scrap | 0.83 | 1.26 |
| secondary, avoided burden | 1.40 | 10.8 |
| scrap, avoided burden | 1.34 | 10.7 |

Eco-efficiency / Climate change intensities

Appropriate Eco-efficiency indicators

- Indicators based on which concept represent eco-efficiency more appropriately?
 - cut-off, or
 - avoided burdens
- Dependent on the definition of the sustainability concept

Cut-off (sunk costs) approach to support strong sustainability

- Choice of materials with a perspective of strong sustainability:

all emissions caused today are booked today,
no burden shift into the far future (no
“environmental loans” from future generations)

=> **Precautionary principle**

it is unsure, whether our descendants need / wish
our “preinvestment” (buildup of a metal stock)

Main differences between “avoided burden” and “cut-off” approach

| | avoided burden | cut-off |
|---|----------------|------------|
| Future utility of material | yes | uncertain |
| Sustainability concept | weak | strong |
| Environ. grants from future generations | yes | no |
| Burden shifting into future | yes | no |
| Risk perception | tolerant | aware |
| Message of Eco-efficiency indicator | prim > sec | sec > prim |

Conclusions

- Different modelling approaches for far future metals recycling exist:
 - Cut-off: strong sustainability, risk aware
 - Avoided burden: weak sustainability, risk tolerant
- Cut off: for public welfare, including interests of future generations
- Avoided burden: allocation of credits between actors is due
- Transparent unit process LCI databases able to serve both approaches
 - > ecoinvent database
